What is a pumped storage power plant?

Pumped storage power plants are used to balance the frequency, voltage and power demands within the electrical grid. Pump storage plants are often utilised to add additional megawatt capacity to the grid during period of high power demand, for this reason, pumped storage plants are referred to as 'peaking' plants.

What is a closed-loop pumped storage hydropower system?

With closed-loop PSH, reservoirs are not connected to an outside body of water. Open-loop pumped storage hydropower systems connect a reservoir to a naturally flowing water feature via a tunnel, using a turbine/pump and generator/motor to move water and create electricity.

Why are interconnecting plants used in water pumping?

Such plants are usually interconnected with steam or diesel engine plants so that off peak capacity of interconnecting stations is used in pumping water and the same is used during peak load periods. Of course, the energy available from the quantity of water pumped water the power available is reduced on account of losses occurring in prime movers.

How does a power plant generate electricity?

They achieve this by allowing water to flow from a high elevation to a lower elevation, or, by pumping water from a low elevation to a higher elevation. When water flows to a lower elevation, the power plant generates electricity. When water is pumped to a higher elevation, the power plant creates a store of potential energy.

What are the advantages and disadvantages of pump storage plants?

Advantages: The pump storage plants entail the following advantages : 1. There is substantial increase in peak load capacity of the plant at comparatively low capital cost. 2. Due to load comparable to rated load on the plant, the operating efficiency of the plant is high. 3. There is an improvement in the load factor of the plant.
